

## MOVABLE CANOPY FOR INFANT CARE APPARATUS

### Abstract

An infant warming apparatus for supporting an infant upon an infant platform. A radiant heater is located above the infant platform at one end thereof. A canopy covers the infant platform and is movable between a closed position where the infant is enclosed and an open position providing access to the infant and/or the radiant heater can be energized to direct infrared energy toward the infant platform. The canopy is constructed of two sections, one of which is pivotally affixed with respect to the infant platform at or proximate the one end and the other section is movable relative the one section to create an open space so that when the canopy is pivoted to its open position past the radiant heater, the radiant heater is aligned with respect to the open space to allow the radiant energy to reach the infant platform without passing through the canopy.
